Abstract

Influence of process variables like pH, adsorbent dosage (D), initial dye concentration (C₀), particle size (S) and temperature (T) on adsorption of a direct dye on carbon derived from mango leaf carbon were studied using a 2⁵ factorial design. The main effects and interaction effects were determined using statistical methods. Maximum uptake obtained was 55.7 mg/g (pH = 2, T = 40 °C, D = 0.5 g/dm³, C₀ = 100 mg/dm³ and S = 53 µm). It was found that the effects of process variables namely pH, adsorbent dosage, initial dye concentration particle size and temperature on dye uptake were statistically significant. In addition, 2-level, 3-level and 4-level interactions between the variables were also found to influence dye uptake significantly. The model explained 96.79% variation in the response leaving only 3.21% for residuals. Dye uptake capacity upto 55.7 mg/g could be obtained with the proposed carbonaceous adsorbent mango leaf char.

Key words: Congo red, direct dye, dye removal, factorial design, mango leaf char
