Abstract

In this study, nine microbial strains with oil-degrading function were isolated from oil-contaminated soil near four oil wells in the 0.6 km^2 area of the Jinnan Oil Field, Huaian, Jiangsu, China ($32^\circ 57'$ N, $119^\circ 02'$ E). Based on morphological observations, physiological and biochemical responses, and molecular identification, we confirmed that the nine strains belong to five genera: *Pseudomonas, Raoultella, Lysinibacillus, Escherichia*, and *Klebsiella*. The degradation capacity of the nine strains in crude oil medium ranged from 2.43% to 32.63% with an average rate of 21.64%. Further plasmid and chromosome analyses on the oil-degrading genes of the nine microbial strains were conducted. The *GST* gene (degradable polycyclic aromatics) was widely distributed in the chromosomes of eight strains and the plasmids of three strains. The *alkB* gene was detected in the chromosomes of seven strains and the plasmids of two strains. The *LmPH* gene (degradable phenolic substances) was only detected in the chromosome of one strain. Molecular biological analyses on the isolation, identification, and degradation characteristics of oil-degrading microbial strains provide a foundation for microbial remediation in oil-polluted environments.

Key words: biodegradation, functional gene analysis, molecular identification, oil pollution
