Abstract

Based on the dynamic panel data from 29 administrative regions in China over the period of 2003-2013, we applied GMM system method to the analysis of the relationship between financial development, economic growth and CO₂ emissions. Empirical analysis indicates that economic growth is usually accompanied by higher CO₂ emissions, while the increasing level of final development is associated with a reduction in CO₂ emissions. Further analysis shows that the relationship between financial development and CO₂ emissions presents an inverted-U shape pattern. Only after the economic development has reached a threshold value will the promoting effect of financial development to the reduction of CO₂ emissions manifest. Moreover, industrial structure optimization and upgrading contribute to the reduction of CO₂ emissions. In other words, the increasing proportion of the secondary sector will weaken the promoting effect of financial development to the reduction of CO₂ emissions and intensify the negative impact of economic growth on CO₂ emissions. On the contrary, the increasing proportion of the tertiary sector will greatly facilitate the reduction of CO₂ emissions and mitigate the increase of CO₂ emissions due to economic growth. For less financially developed countries, market-oriented reform can reduce carbon emissions by promoting financial development. Moreover, industrial structure optimization and upgrading will contribute significantly to the reduction of CO₂ emissions.

Key words: CO₂ emissions, economic growth, financial development, industrial structure
