Abstract

Air pollutants have harmful effects on the human health and exacerbate morbidity and mortality. The aim of this study is to assess the short- and long-term effects of the suspended particulate matter with the diameter of smaller than 2.5 μm (PM$_{2.5}$), nitrogen dioxide (NO$_2$), and ozone (O$_3$) on the mortality cases in the city of Kerman in 2016 and 2017. In this study, AirQ+ software presented by European Center for Environment and Health and World Health Organization (WHO) was employed. Daily mean concentration of PM$_{2.5}$, mean hourly concentration of NO$_2$, and maximum 8-h O$_3$ concentration were used to assess the health impact of human exposure to these pollutants. The mean concentration of PM$_{2.5}$, NO$_2$, and O$_3$ in the studied years was higher than the WHO guideline and the mean concentration of NO$_2$ and O$_3$ was less than the WHO guideline. In the short-term health impact assessment, the death caused by stroke in individuals above 25 years old due to O$_3$ had the highest attributable proportion with 2.48% in 2016 and 2.39% in 2017. Also, in the long-term health impact assessment, the highest attributable proportion for natural death caused by PM$_{2.5}$ was 15.24% in 2016 and 15.15% in 2017. In general, exposure to air pollutants is a risk factor; therefore, the implementation of sustainable control policies including population growth, urbanization, and traffic control is suggested to avoid the health impacts and economic damages.

Key words: air pollution, health outcomes, long-term impact, meteorological, mortality, short-term impact
